Relación entre Índice de Masa Corporal (IMC) y Enfermedad TromboEmbólica (ETV)

Dra Raquel Barba Martín

Fundación Hospital Alcorcón

$$IMC = \frac{peso\ (kg)}{[talla\ (m)]^2}$$

Medida antropométrica que relaciona el peso con la talla de un individuo

$$IMC = peso\ (kg)\ /\ [talla\ (m)]^2$$

- IMC< 16 (riesgo vital)
- IMC <18.5 (delgado)
- IMC 18,5-24,9 kg/m^2 (normalidad).
- IMC 25-29,9 kg/m^2 (sobrepeso)
- IMC > 30 kg/m^2 (obesidad)
- IMC>40 kg/ m^2 (obesidad mórbida)

Fórum Multidisciplinar de la
Enfermedad
Tromboembólica

$$IMC = peso\ (kg)\ /\ [talla\ (m)]^2$$

- Existen diversos estudios epidemiológicos que han puesto en relación en Indice de Masa Corporal y la mortalidad, tanto en poblaciones generales como en grupos de pacientes con patologías concretas.

- En general, en la mayoría de los estudio se demuestra una relación en 'J' o 'U' de Sharp entre mortalidad e IMC

Fórum Multidisciplinar de la

BODY-MASS INDEX AND MORTALITY IN A PROSPECTIVE COHORT
OF U.S. ADULTS

EUGENIA E. CALLE, PH.D., MICHAEL J. THUN, M.D., JENNIFER M. PETRELLI, M.P.H., CARMEN RODRIGUEZ, M.D., M.P.H.,
AND CLARK W. HEATH, JR., M.D.

- 457.785 hombres y 588.369 mujeres, mayores de 30 años y con una edad promedio de 57, fueron seleccionados del Cancer Preventive Study II (un estudio de mortalidad llevado a cabo por la American Cancer Society).

- Los participantes habían completado un cuestionario en 1982 y se registraron todas las muertes ocurridas hasta diciembre de 1996.

Relación Mortalidad- IMC

- IMC: se estratificó en categorías desde menor de 18.5 hasta mayor o igual a 40.0.

- Se establecieron subgrupos de riesgo en base a la:
  - presencia tabaquismo (TBQ)
  - ausencia de tabaquismo (TBQ)
  - presencia enfermedades concomitantes [EC] (cáncer, ACV, ECV, respiratoria, cualquier otra enfermedad y perdida de peso de 4.5 kg en el año previo).
  - ausencia de dichas enfermedades [EC]

No TBQ ni EC
No TBC si EC
Si TBQ no EC
Si TBQ si EC

E Calle et al. Body-mass index and mortality in a prospective cohort of US adults. The New England Journal of Medicine 1999 341: 1097-1105.

- Las tasas de mortalidad se expresaron en riesgo relativo comparando cada categoría de IMC con la de referencia: **23.5- 24.9**.

- Para cada uno de los cuatro subgrupos se midió asociación entre IMC y mortalidad de acuerdo al sexo.

Figure 1: Relative risk of all cause death for men who never smoked and who had no history of disease

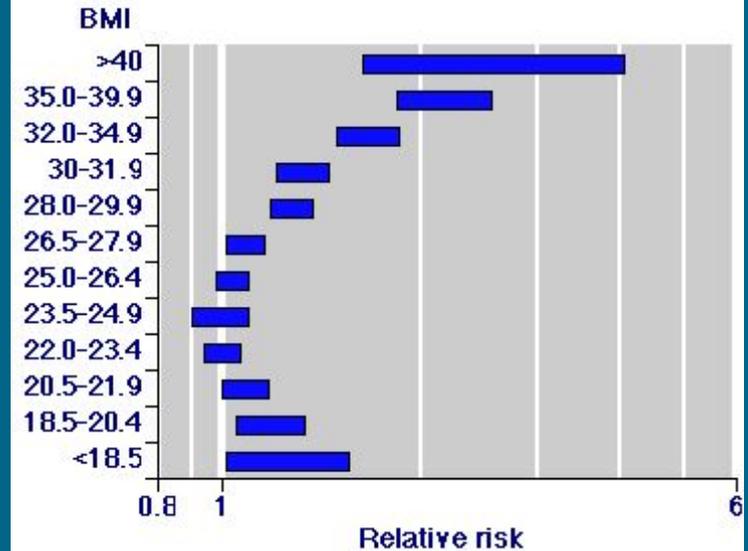

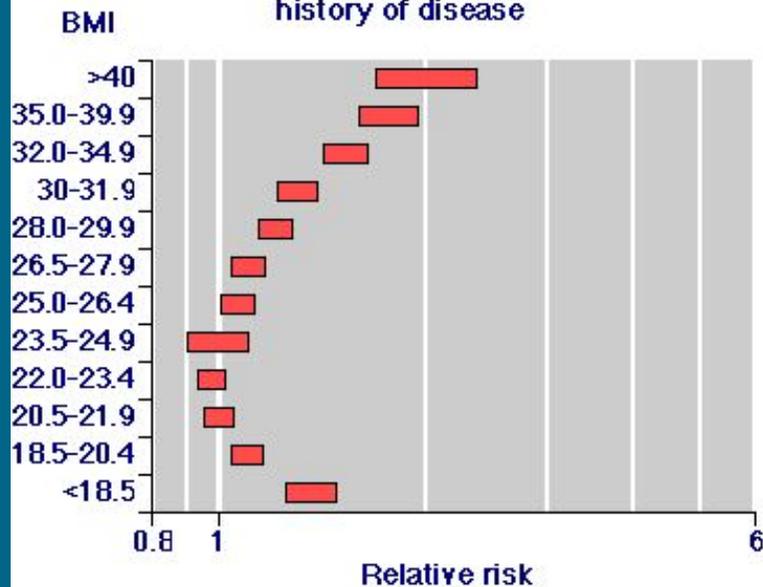

Figure 2: Relative risk of all cause death for women who never smoked and who had no history of disease
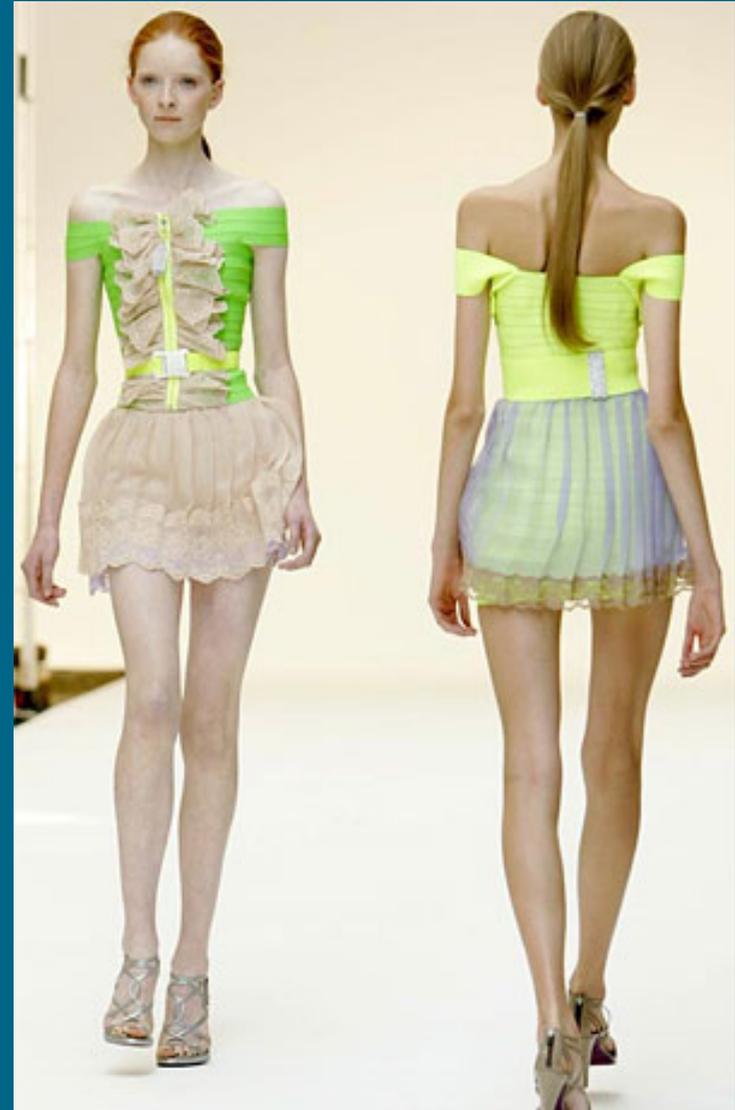

Relación Mortalidad- IMC

Las conclusiones más relevantes del estudio:

1.- Los pacientes con **IMC mínimo** tenían más riesgo de fallecer que el grupo de referencia

*RR 1.28 (IC 95% 1.04-1,58) en hombres

*RR 1.36 (IC 95% 1.26-1.48) en mujeres

Relación Mortalidad- IMC

2.- Un **alto IMC** fue predictor de muerte especialmente en hombres, donde se observó un RR para la categoría de máximo IMC de 2.90 (IC 95% 2.37- 3.56) en relación con el grupo de referencia

Relación IMC y diferentes patologías

- Se ha estudiado la relación existente en el pronóstico en diferentes enfermedades y el IMC:
  - cáncer de colon,
  - cáncer ovario,
  - cáncer pulmón,
  - enfermedad cardiovascular,
  - pacientes ingresados en UCI

Obesity as a risk factor in venous thromboembolism

Paul D. Stein, MD,[a,b] Afzal Beemath, MD,[a] Ronald E. Olson, PhD[c]

ABSTRACT

PURPOSE: Whether obesity is an independent risk factor for pulmonary embolism or deep venous thrombosis has not been fully determined.

METHODS: We used the database of the National Hospital Discharge Survey to further investigate the potential risk of obesity in venous thromboembolic disease.

RESULTS: The relative risk of deep venous thrombosis, comparing obese patients with non-obese patients, was 2.50 (95% confidence interval [CI] = 2.49-2.51). The relative risk of pulmonary embolism was 2.21 (95% CI = 2.20-2.23). Obese females had a greater relative risk for deep venous thrombosis than obese males, 2.75 (95% CI = 2.74-2.76) versus 2.02 (95% CI = 2.01-2.04). Obesity had the greatest impact on both men and women aged less than 40 years.

CONCLUSION: The data indicate that obesity is a risk factor for venous thromboembolic disease in men as well as women.

IMC y ETV

- **No** existía ningún estudio que hubiera relacionado la enfermedad tromboembólica con el índice de masa corporal bajo.

Relación IMC y ETV

Existe una relación lineal **inversa** entre el IMC y la mortalidad

Los pacientes con IMC bajo tienen más riesgo de fallecer en el seguimiento

Los pacientes con IMC elevado tienen un riesgo menor de fallecer a los 3 meses del evento

Relación IMC y ETV

- No existe ninguna explicación clara a este fenómeno

- Por lo general la obesidad es un factor de mal pronóstico en la mayoría de las patologías en las que se ha estudiado, con una magnitud más o menos marcada en función de los pacientes estudiados.

Body Weight and Mortality Among Men and Women in China

Figure. Multivariate-Adjusted Relative Risks of All-Cause Mortality According to Categories of Body Mass Index by Age and Health Status

Error bars indicate 95% confidence intervals. The high-risk participants included those who had prevalent cardiovascular disease, stroke, cancer, end-stage renal disease, or chronic obstructive pulmonary disease at the baseline examination, or who were heavy alcohol drinkers (consumed ≥3 drinks per day), or who were cigarette smokers. Multivariate-adjusted relative risk was calculated using study participants with a body mass index (calculated as weight in kilograms divided by square of height in meters) of 24.0 to 24.9 as the reference group, adjusted for age, sex, cigarette smoking, alcohol consumption, physical activity, education, geographic region (north vs south), and urbanization (urban vs rural), and stratified by sampling clusters. All P values for the quadratic term were significant (P<.001).

Conclusions Our results indicate that both underweight and obesity were associated with increased mortality in the Chinese adult population. Furthermore, our findings support the use of a single common recommendation for defining overweight and obesity among all racial and ethnic groups.

Comparison of weight in middle age, weight at 18 years, and weight change between, in predicting subsequent 14 year mortality and coronary events: Caerphilly Prospective Study

John W G Yarnell, Christopher C Patterson, Hugh F Thomas, Peter M Sweetnam

Conclusions—Body mass at 18 years of age of 30 kg/m² or more conferred increased risk for all cause mortality and major ischaemic heart disease during 14 years of follow up of men aged 45 to 59 years. By the baseline examination the prevalence of obesity (body mass index ≥30) had increased from 1.8% to 12.1%; obese men also showed an excess risk of major ischaemic heart disease and overall mortality, but these risks were lower than those predicted from 18 years of age.

Table 1 Risk of death or a coronary event in the 14 years after screening examination in fifths of the distribution of body mass index at 18 years of age

Body mass index fifths (kg/m²)	Number of men	Number of deaths (%)	Relative odds of death (95% CI)*	Number of coronary events (%)	Relative odds of coronary event (95% CI)*
<20.1	467	88 (19%)	1.00	60 (13%)	1.00
20.1 to 21.5	467	84 (18%)	0.94 (0.67, 1.32)	78 (17%)	1.41 (0.97, 2.04)
21.6 to 22.7	467	83 (18%)	0.89 (0.63, 1.25)	66 (14%)	1.12 (0.76, 1.63)
22.8 to 24.1	467	96 (21%)	1.03 (0.74, 1.45)	83 (18%)	1.43 (0.99, 2.06)
≥24.2 –	467	114 (24%)	1.29 (0.93, 1.79)	95 (20%)	1.73 (1.21, 2.48)
		Likelihood ratio	$\chi^2 = 5.91$; df = 4; p = 0.21	Likelihood ratio	$\chi^2 = 11.47$; df = 4; p = 0.02

*Relative odds adjusted for age, smoking habit and social class.

Table 2 Risk of death or a coronary event in the 14 years after screening examination in obese and non-obese men at 18 years of age

Body mass index	Total	Number (%) of men	
		Dead	With coronary event
Less than 30	2294	451 (20%)	370 (16%)
30 or more	41	14 (34%)	12 (29%)

Conclusion Weight gain from age 20, even a very moderate increase, is strongly associated with an increased risk of coronary death and non-fatal myocardial infarction.

Table 2   Death from coronary disease and all causes by body mass index at baseline

Cause of death	No at risk	Deaths per 1000 person years (number of deaths)	Age-adjusted relative risk	Relative risk adjusted for age, physical activity, and smoking	Relative risk adjusted for age and other cardiovascular risk factors*
Coronary disease					
Body mass index (kg . m^{-2})					
<20	194	7·1 (23)	1·56 (0·97–2·50)	1·34 (0·83–2·18)	1·48 (0·91–2·41)
20–22·5	877	4·4 (76)	1·00	1·00	1·00
22·5–25·0	2093	4·3 (181)	0·96 (0·73–1·25)	1·05 (0·80–1·37)	0·99 (0·76–1·30)

*Adjusted for age, smoking habit, serum cholesterol, systolic blood pressure, physical activity, and diabetes.

Relación IMC y ETV

Relación IMC y ETV

Podemos explicar la mayor mortalidad en pacientes de bajo peso

- porque hablemos de pacientes enfermos (bajo peso como marcador de enfermedad)

- por tendencia a sobredosificar a esos pacientes

Relación IMC y ETV

-Parece más difícil la explicación de la obesidad como 'protector' en pacientes con ETV

-Es probable que la ETV en pacientes obesos se deba básicamente a problemas venosos 'locales', mientras que la ETV de pacientes más delgados nos esté reflejando otros problemas de salud 'sistémicos'

-Habrá que seguir investigando esta relación para poder encontrar explicaciones a este 'fenómeno'

Body Mass Index and Risk of Suicide Among Men

Kenneth J. Mukamal, MD, MPH, MA; Ichiro Kawachi, MD, PhD; Matthew Miller, MD, MPH, ScD; Eric B. Rimm, ScD

Background: Body mass index (BMI; calculated as weight in kilograms divided by height in meters squared) has been linked to depression and the risk of suicide attempts and deaths in conflicting directions.

Methods: In a prospective cohort study of 46 755 men free of cancer enrolled in the Health Professionals Follow-up Study, participants reported their height, weight, diet, and physical activity on repeated occasions beginning in 1986 and were followed up until death or until February 2002. A subsample of 1829 men reported their mental health–related quality of life with the Mental Component Summary Scale of the 36-Item Short-Form Health Survey in 1998.

Results: A total of 131 men died from suicide during follow-up. A higher BMI was related to a graded decline in the suicide mortality rate, from 52 per 100 000 person-years among men with a BMI of less than 21 to 13 per 100 000 among men with a BMI of 30 or higher; the adjusted hazard ratio per 1-U BMI increment was 0.89 (95% confidence interval, 0.84-0.95; $P<.001$). The relationship was consistent when baseline or updated measures of BMI were used and with adjustment for medical illness, dietary factors, antidepressant use, physical activity, or social support. Height and physical activity were not strongly associated with risk. Analyses of mental health–related quality of life showed a similar positive relationship with BMI.

Conclusions: Among men, risk of death from suicide is strongly inversely related to BMI, but not to height or to physical activity. Although obesity cannot be recommended on the basis of its detrimental effects, further research into the mechanisms of lower risk among overweight and obese men may provide insights into effective methods of suicide prevention.
