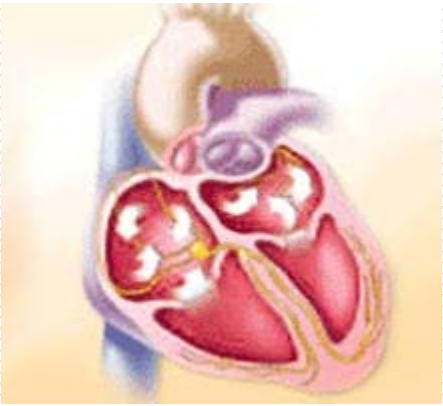
La repercusión de la fibrilación auricular

Francesc Formiga

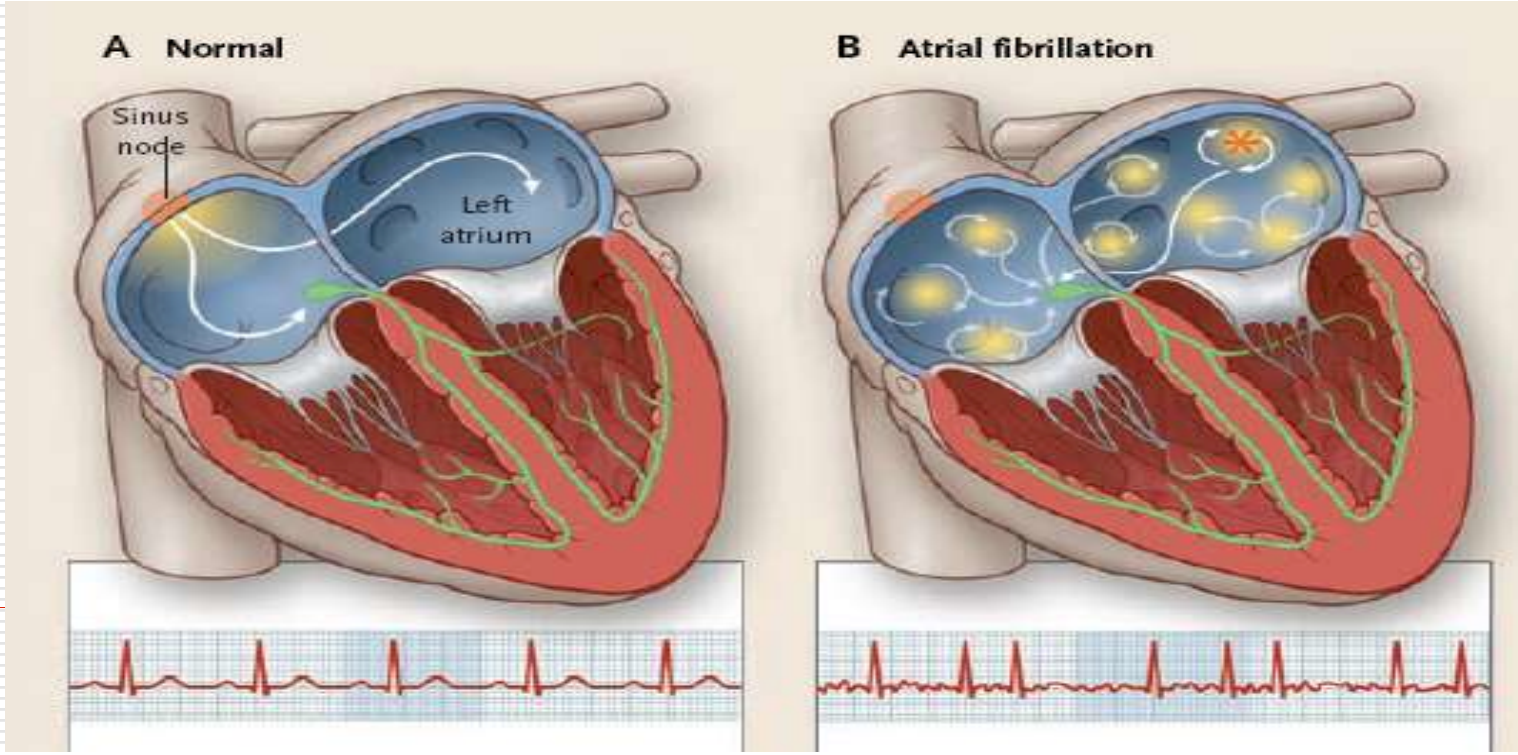
Servicio de Medicina Interna

Hospital Universitari de Bellvitge



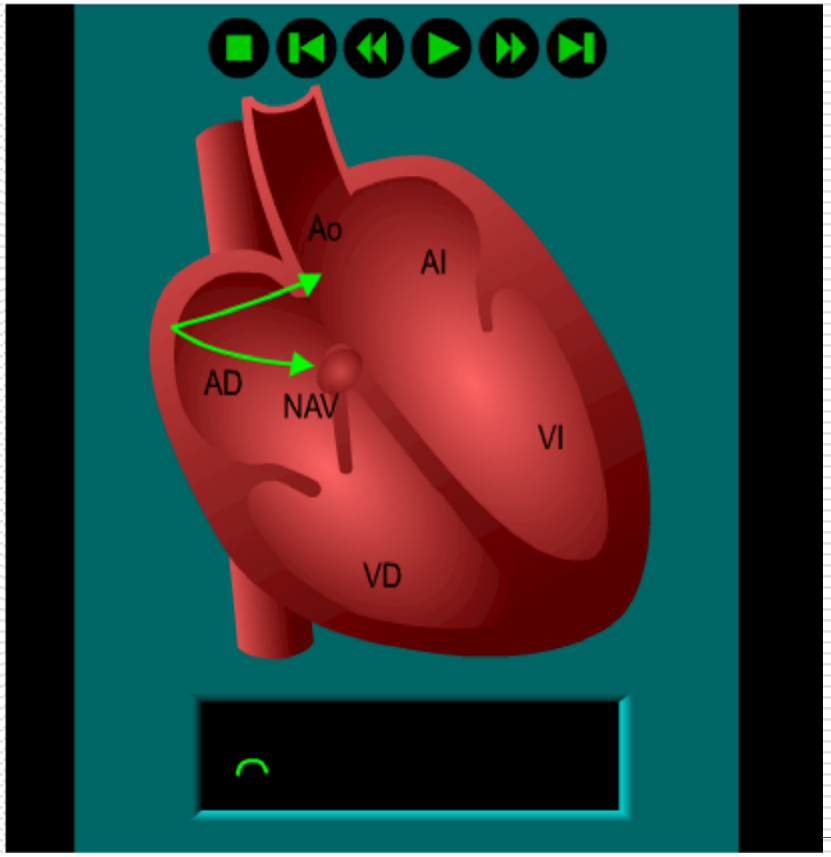
Definición

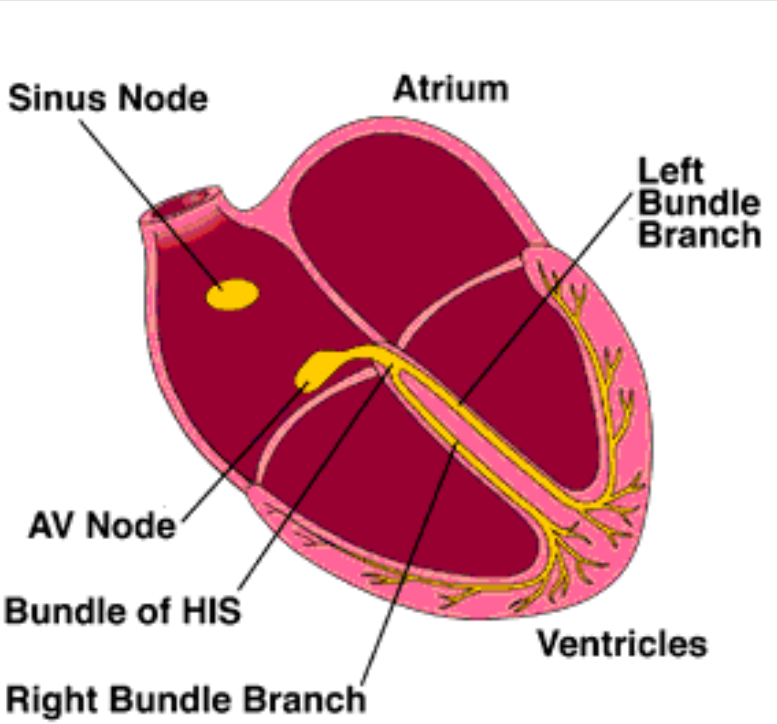
La fibrilación auricular (FA) es una arritmia auricular caracterizada por la activación auricular incoordinada con pérdida de la función de marcapasos por parte del nodo sinusal, con el consiguiente deterioro de la función mecánica auricular.



Definición

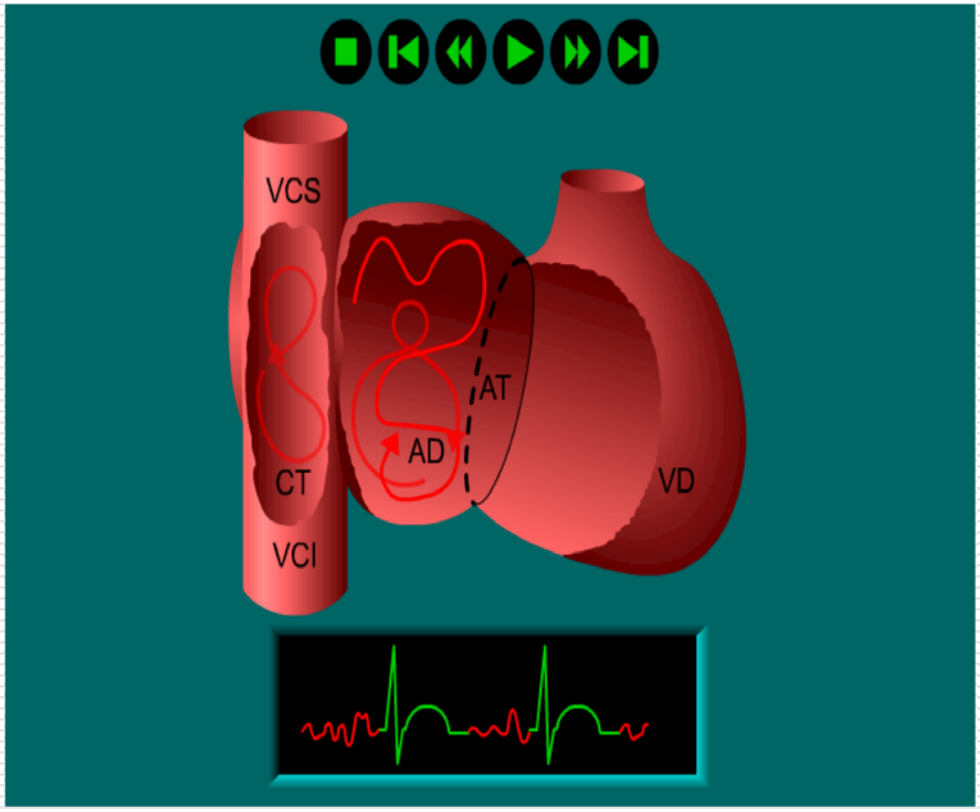
Ritmo normal cardiaco=RITMO SINUSAL

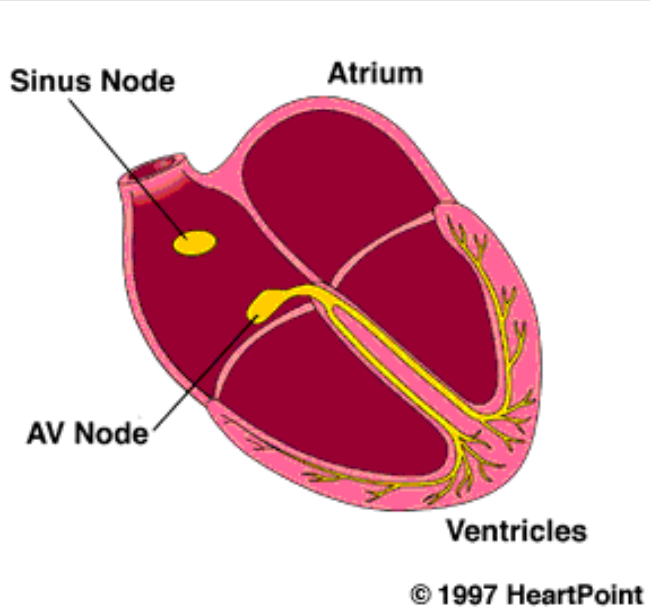




Definición

FIBRILACIÓN AURICULAR= ARRITMIA





Definición

El registro ECG se caracteriza por:

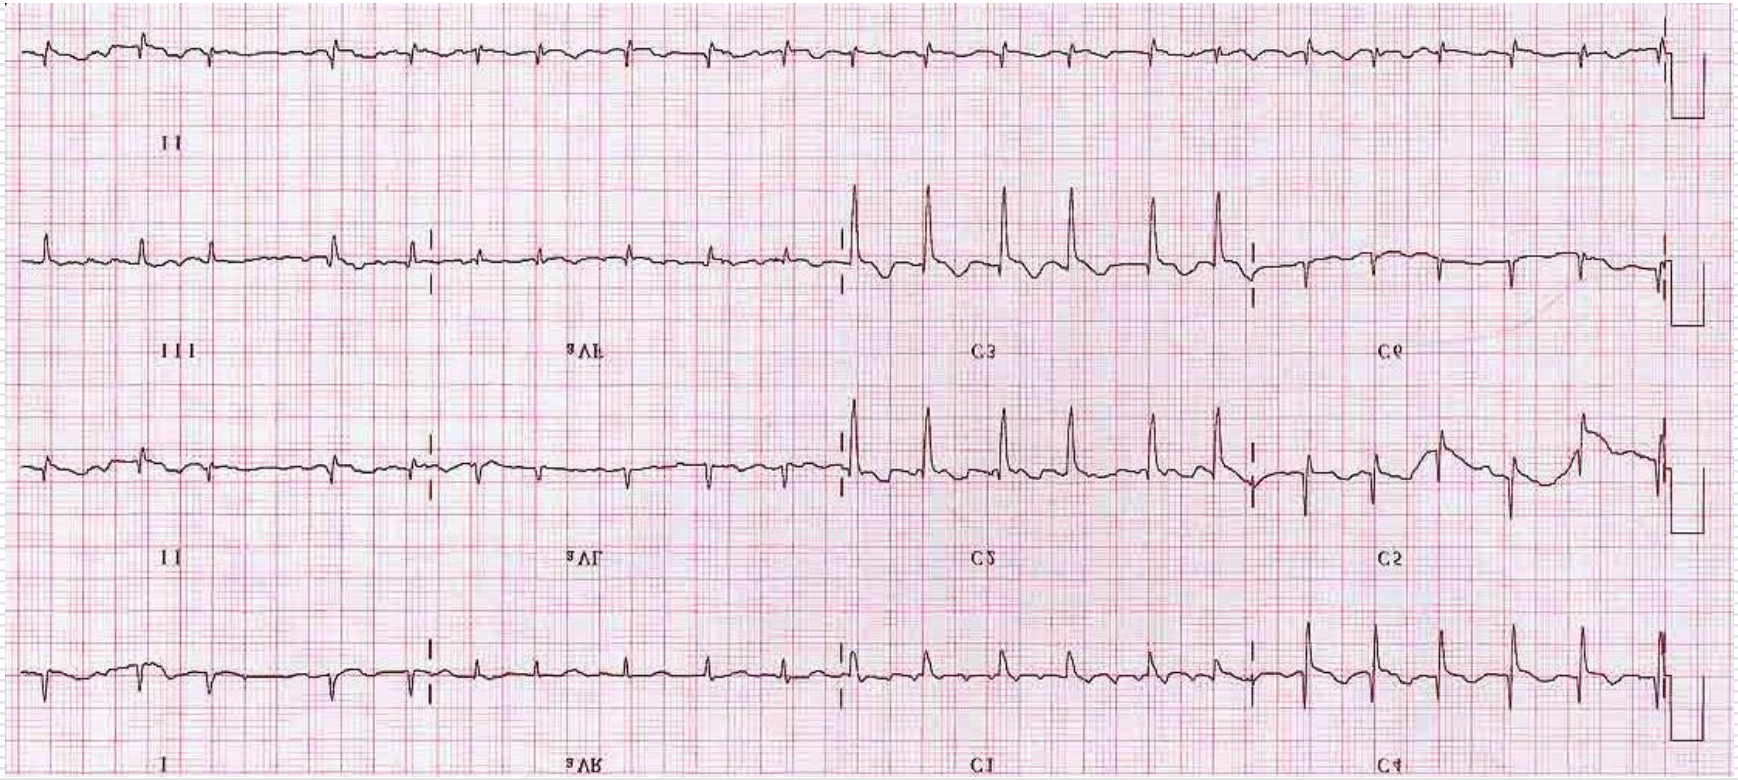
1-Desaparición de ondas P y la sustitución de estas por oscilaciones rápidas e irregulares que modifican la línea de base.

2-Actividad ventricular irregular cuya frecuencia es variable, aunque suele ser rápida en ausencia de tratamiento.

3-Complejos QRS estrechos, si no existe bloqueo de rama.

4-Intervalos RR irregulares

Fibrilación auricular : ECG

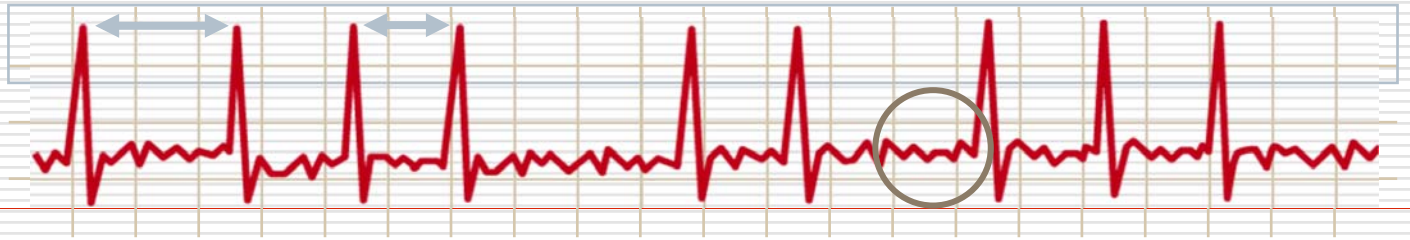


ECG: La señal evidente de la FA es la ausencia de ondas P en el ECG

- En el ECG las ondas P son reemplazadas por oscilaciones rápidas u ondas fibrilatorias que varían en amplitud, forma y momento de aparición.
- Hay una respuesta ventricular irregular que es rápida cuando la conducción no se ha alterado.

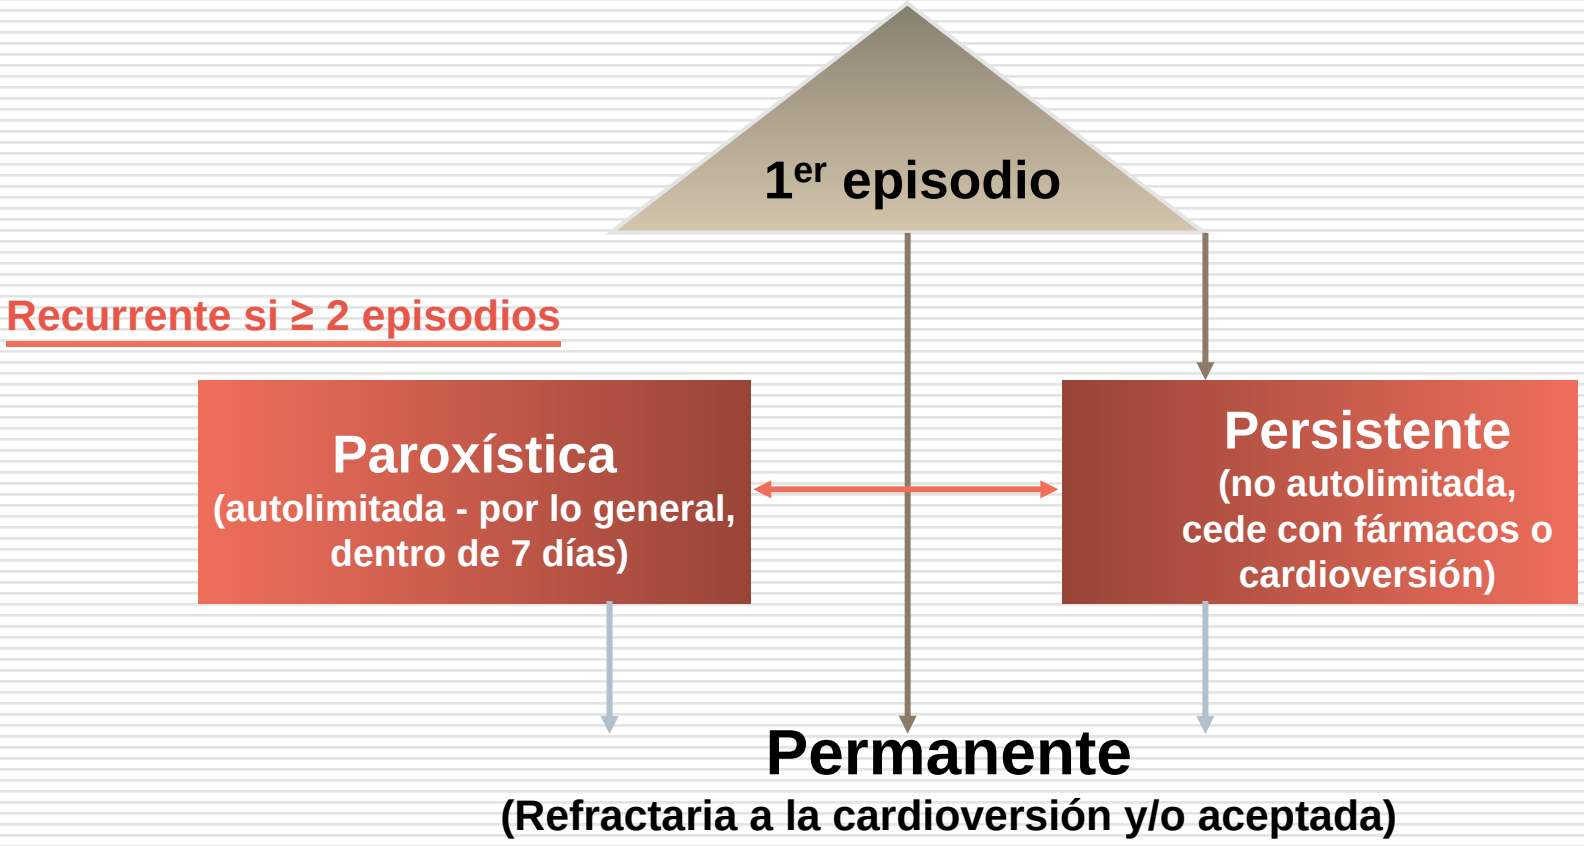
Ritmo sinusal

Fibrilación auricular



ACC/AHA/ESC 2006 guidelines J Am Coll Cardiol 2006;48:854-906

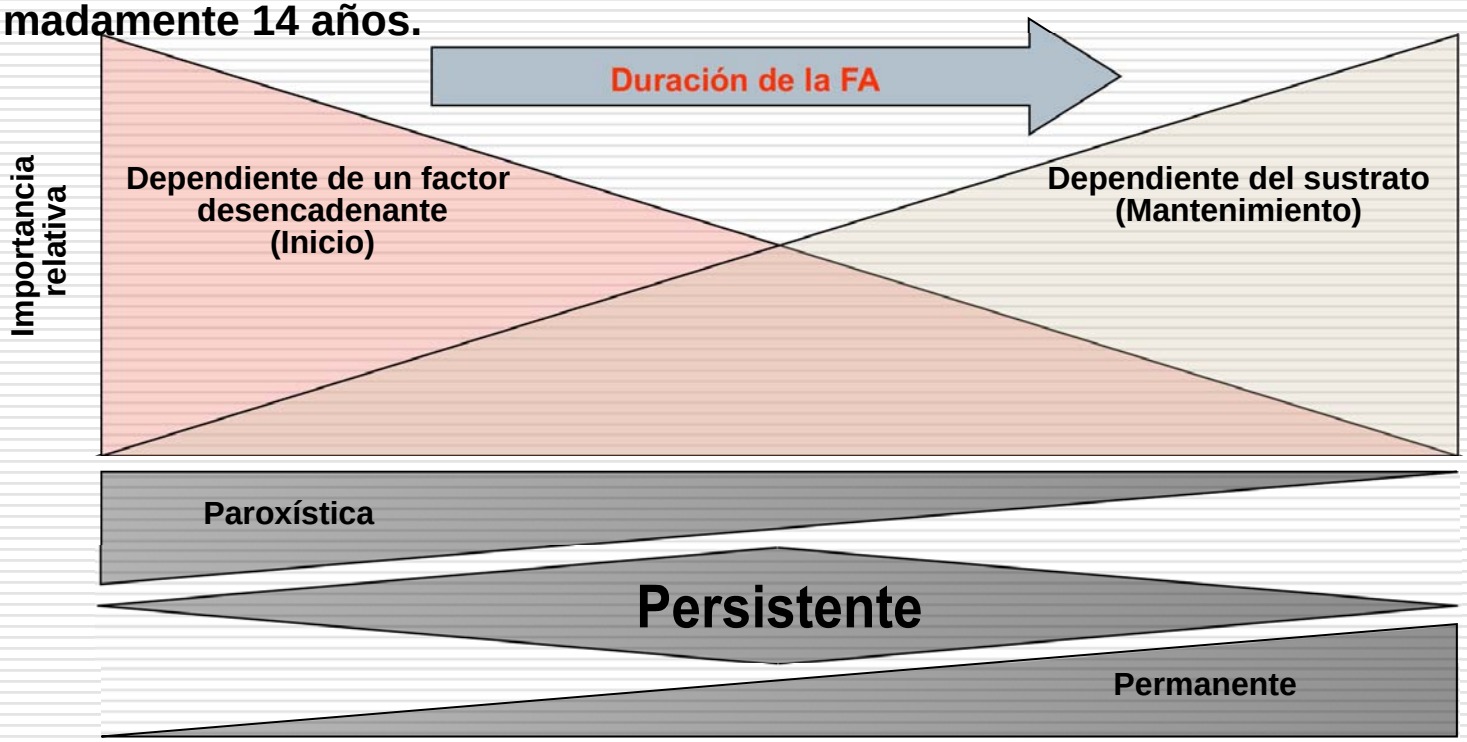
La FA se clasifica en función de la duración del episodio y de la capacidad de recuperar el ritmo sinusal



ACC/AHA/ESC 2006 guidelines *J Am Coll Cardiol* 2006;48:854-906

La fibrilación auricular es una enfermedad progresiva

En el 20% de los pacientes con FA recurrente se vuelve permanente después de 4 años, y en el 77% de los pacientes con FA paroxística esta es permanente después de aproximadamente 14 años.



Khan IA. Int J Card. 2003;87:301-2; Kato et al. Circ J 2004;68:568-72

FIBRILACIÓN AURICULAR
FISIOPATOLOGIA

MECANISMOS

Macroentrada

Microentrada

EFECTOS HEMODINÁMICOS

Pérdida del sincronismo atrioventricular.

Incremento de la presión media auricular

Acortamiento de la diástole

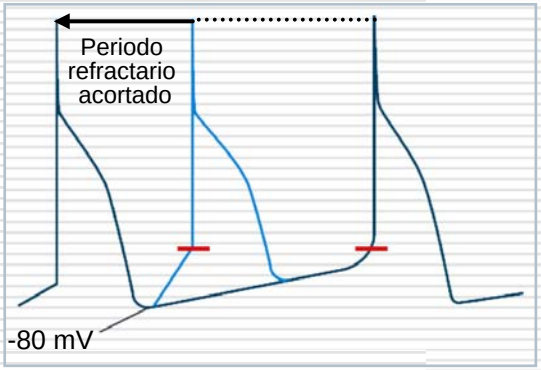
Decrecimiento del flujo coronario

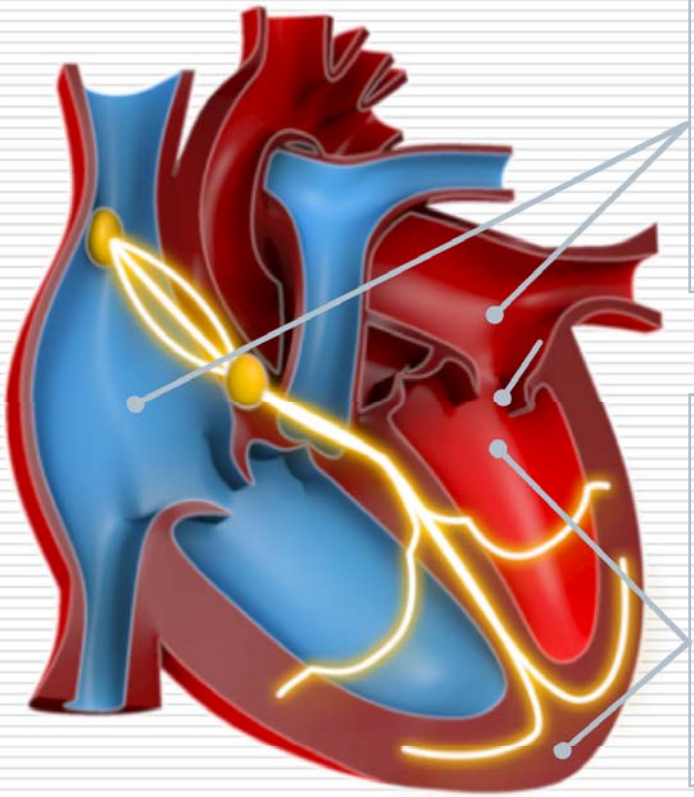
Miocardiopatía por taquicardia

Remodelación cardíaca

Con el tiempo, la FA causa remodelado auricular

- **Remodelado eléctrico**
  - Acortamiento de los periodos refractarios auriculares
  - Se produce rápidamente (en varios días) y contribuye a la mayor estabilidad de la FA





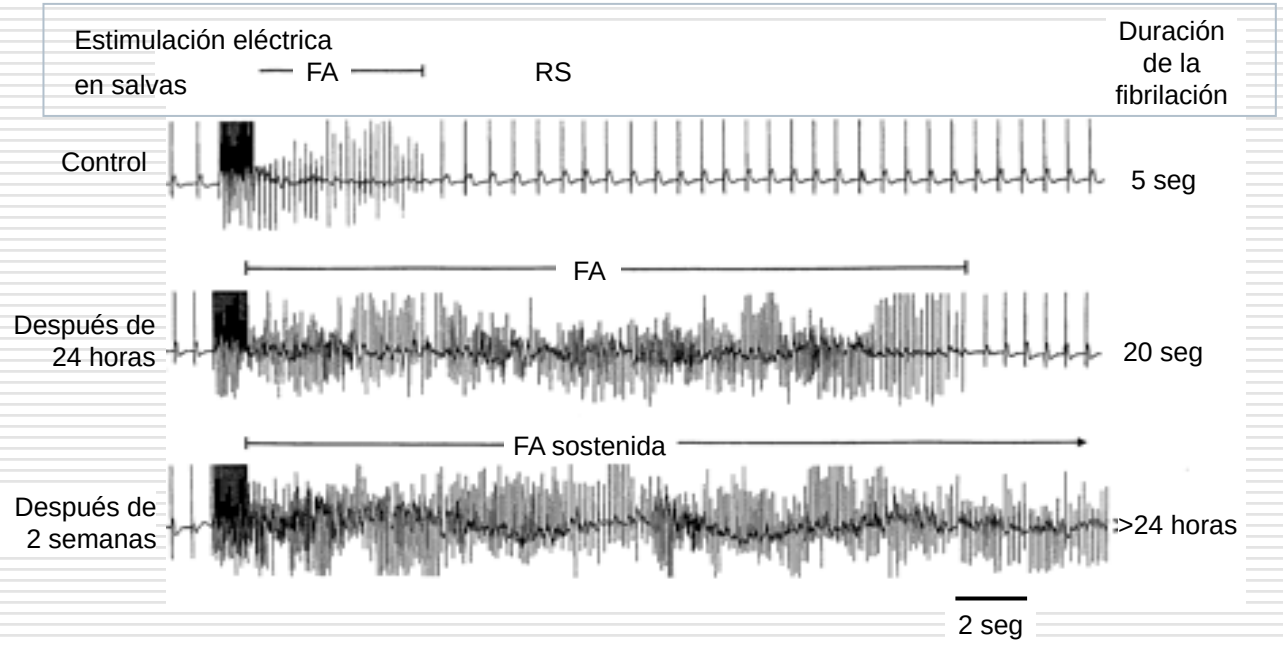
- **Remodelado contráctil**
  - Contractilidad auricular reducida
  - Ectasia sanguínea y formación de trombos
  - Puede llevar a una dilatación auricular que altera aún más sus propiedades electrofisiológicas
  - Se produce rápidamente

- **Remodelado estructural**
  - Cambios histológicos
  - Agrandamiento de la aurícula izquierda y de la orejuela auricular izquierda
  - Disminución del gasto cardiaco
  - Ocurre después de un periodo de semanas a meses

Van Gelder *et al. Europace* 2006;8:943-949

El remodelado auricular estimula aún más la FA

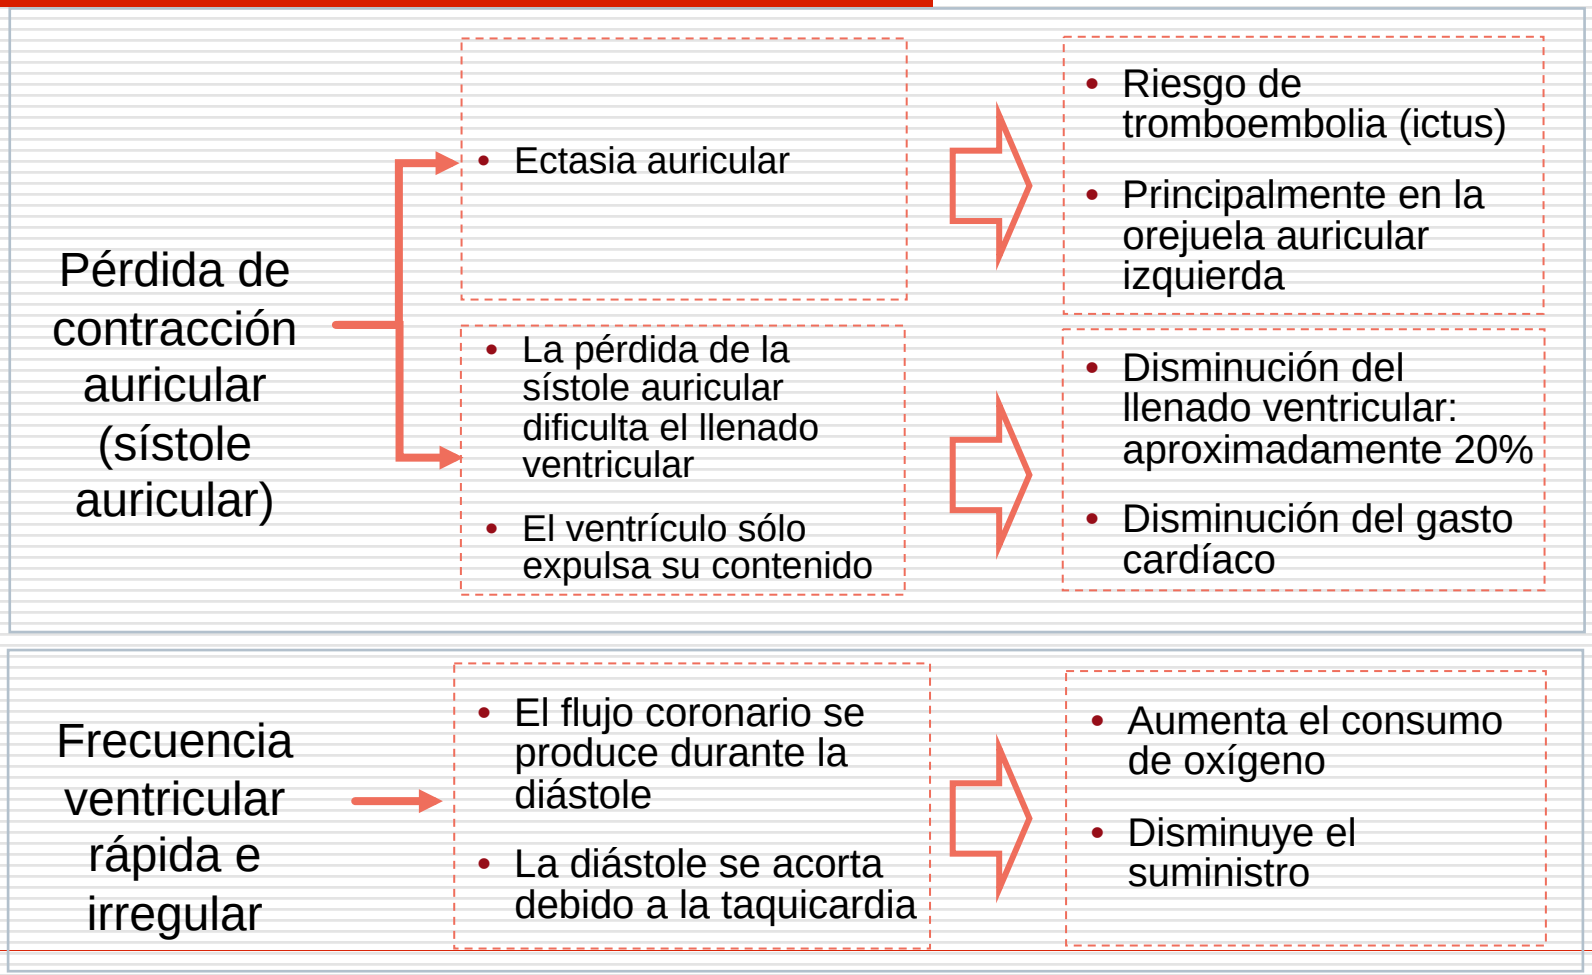
- La FA produce cambios electrofisiológicos que estimulan aún más la FA[1]
- Esos cambios son la causa y la consecuencia del remodelado auricular eléctrico, contráctil y estructural, y se producen en cuestión de días[2]



Estudio en animales de experimentación

1. Wijffels MCEF, *et al. Circulation*. 1995;92:1954-1968.
2. Schotten U, *et al. Circulation*. 2003;107:1433-1439.

El gasto cardíaco disminuye y el riesgo de tromboembolia aumenta



ACC/AHA/ESC 2006 guidelines *J Am Coll Cardiol* 2006;48:854-906

La FA puede dar lugar a miocardiopatía inducida por taquicardia

- Una frecuencia ventricular permanentemente elevada en la FA puede aumentar de manera negativa la regurgitación mitral y provocar miocardiopatía inducida por taquicardia

- El corazón se agranda y tiene un ventrículo izquierdo delgado y debilitado, lo que da lugar a una reducción de su capacidad funcional

- Se desconocen todavía los mecanismos concretos, pero puede deberse a:
  - Depleción de energía miocárdica
  - Isquemia
  - Regulación alterada del calcio
  - Remodelado

ACC/AHA/ESC 2006 guidelines *J Am Coll Cardiol* 2006;48:854-906

Causas de la fibrilación auricular

Independent Contribution of Diabetes to Increased Prevalence and Incidence of Atrial Fibrillation

GREGORY A. NICHOLS, PHD[1]
KYNDARON REINIER, PHD[2]
SUMEET S. CHUGH, MD[2]

OBJECTIVE — Diabetes has long been recognized as a risk factor for atrial fibrillation, but its independent contribution to atrial fibrillation has not been fully evaluated. We sought to compare the prevalence and incidence of atrial fibrillation in age- and sex-matched patients with and without type 2 diabetes.

RESEARCH DESIGN AND METHODS — Using an observational cohort design, we selected 10,213 members of an HMO diabetes registry as of 1 January 1999 plus 7,159 patients who entered the registry by 31 December 2004 and matched them to patients without diabetes on year of birth and sex. All patients were followed until they died, left the health plan, or until 31 December 2008. We compared the baseline prevalence of atrial fibrillation and then followed patients without atrial fibrillation to compare atrial fibrillation incidence while controlling for known risk factors.

RESULTS — Atrial fibrillation prevalence was significantly greater among patients with diabetes (3.6 vs. 2.5%, $P < 0.0001$). Over a mean follow-up of 7.2 ± 2.8 years, diabetic patients without atrial fibrillation at baseline developed atrial fibrillation at an age- and sex-adjusted rate of 9.1 per 1,000 person-years (95% CI 8.6–9.7) compared with a rate of 6.6 (6.2–7.1) among nondiabetic patients. After full adjustment for other risk factors, diabetes was associated with a 26% increased risk of atrial fibrillation among women (hazard ratio 1.26 [95% CI 1.08–1.46]), but diabetes was not a statistically significant factor among men (1.09 [0.96–1.24]).

CONCLUSIONS — In this population, diabetes was an independent determinant of atrial fibrillation prevalence but predicted incidence only among women. These findings have potential public health implications and emphasize the need for further investigation of the mechanistic links between diabetes and atrial fibrillation.

ORIGINAL INVESTIGATION

Glucocorticoid Use and Risk of Atrial Fibrillation or Flutter

A Population-Based, Case-Control Study

Christian Fynbo Christiansen, MD; Steffen Christensen, MD; Frank Mehnert, MSc; Steven R. Cummings, MD; Roland D. Chapurlat, MD, PhD; Henrik Toft Sørensen, MD, PhD, DMSc

Background: Glucocorticoid use is associated with increased risk of myocardial infarction, stroke, and heart failure, but data are limited on the risk of atrial fibrillation or flutter. We examined whether glucocorticoid use is associated with the risk of atrial fibrillation or flutter.

Methods: For this population-based, case-control study, we identified all patients with a first hospital diagnosis of atrial fibrillation or flutter from January 1, 1999, through December 31, 2005, in Northern Denmark (population, 1.7 million). For each case we selected 10 population controls matched by age and sex. We obtained data on glucocorticoid prescriptions within 60 days (current users) or longer before the index date (former users), comorbidity, and medications from medical databases. We used conditional logistic regression to compute odds ratios (ORs), controlling for potential confounders.

Results: Among 20 221 patients with atrial fibrillation or flutter, 1288 (6.4%) were current glucocorticoid users and 2375 (11.7%) were former users. Among 202 130 population controls, 5245 (2.6%) were current glucocorticoid users and 19 940 (9.9%) were former users. Current glucocorticoid use was associated with an increased risk of atrial fibrillation or flutter compared with never use (adjusted OR, 1.92; 95% confidence interval [CI], 1.79-2.06). Among new glucocorticoid users, the adjusted OR was 3.62 (95% CI, 3.11-4.22) and among long-term users it was 1.66 (95% CI, 1.53-1.80). The increased risk remained robust in patients with and without pulmonary and cardiovascular diseases. Former glucocorticoid use was not associated with increased risk (adjusted OR, 1.00; 95% CI, 0.96-1.06).

Conclusion: Current glucocorticoid use was associated with an almost 2-fold increased risk of atrial fibrillation or flutter.

Received 23 July 2009; revised 5 August 2009; accepted 12 August 2009; online publish-ahead-of-print 30 August 2009

See page 2302 for the commentary on this article (doi:10.1093/eurheartj/ehp362)

Aims This ancillary analysis of the GISSI-HF database aims at assessing the effect of rosuvastatin on the occurrence of atrial fibrillation (AF) in patients with chronic heart failure (HF) who were not in AF at study entry.

Methods and results GISSI-HF was a double-blind, placebo-controlled trial testing n-3 PUFA and rosuvastatin vs. corresponding placebos in patients with chronic HF. Atrial fibrillation occurrence was defined as the presence of AF in the electrocardiogram (ECG) performed at each visit during the trial or AF as a cause of worsening HF or hospital admission or as an event during hospitalization. Among the 3690 patients (80.7%) without AF on their baseline ECG, 15.0% developed AF during a median follow-up period of 3.7 years, 258 randomized to rosuvastatin (13.9%) vs. 294 allocated to placebo (16.0%). Although the difference was not significant at unadjusted analysis ($P = 0.097$) and multivariable analysis adjusting for clinical variables ($P = 0.067$), it became significant after adjustment for clinical variables and laboratory examinations ($P = 0.039$), and for clinical variables, laboratory examinations, and background therapies ($P = 0.038$).

Conclusion This study shows that there is some evidence of a beneficial effect of rosuvastatin in terms of reduction of AF occurrence in patients with HF. Larger populations are needed to provide a definite answer to the question.
ClinicalTrials.gov Identifier: NCT00336336

Statins for prevention of atrial fibrillation after cardiac surgery: A systematic literature review

Oliver J. Liakopoulos, MD,[a,b] Yeong-Hoon Choi, MD,[a,b] Elmar W. Kuhn, MD,[a] Thorsten Wittwer, MD,[a,b] Michal Borys, MD,[a] Navid Madershahian, MD,[a] Gernot Wassmer, PhD,[c] and Thorsten Wahlers, MD[a,b]

Objective: To determine the strength of evidence of preoperative statin therapy for prevention of atrial fibrillation after cardiac surgery.

Methods: A meta-analysis was performed of randomized controlled trials and observational trials reporting the impact of preoperative statin therapy on the incidence of any type and new-onset atrial fibrillation after cardiac surgery. Unadjusted and adjusted treatment effects (odds ratio, 95% confidence intervals) were pooled using a random-effects model, and publication bias was assessed.

Results: Thirteen studies were identified (3 randomized controlled trials, 10 observational trials) that reported the incidence of postoperative atrial fibrillation in 17,643 patients having cardiac surgery with (n = 10,304; 58%) or without (n = 7339; 42%) preoperative statin use. New-onset atrial fibrillation was reported in a total of 7855 patients. Postoperative incidence rates for any or new-onset atrial fibrillation were 24.6% and 29.9%, respectively. Preoperative statin use resulted in a 22% and 34% unadjusted odds reduction for any atrial fibrillation (odds ratio, 0.78; 95% confidence interval, 0.67–0.90) or new-onset atrial fibrillation (odds ratio, 0.66; 95% confidence interval, 0.51–0.84) after surgery ($P < .001$). Relevant publication bias and an unequal distribution of confounding variables favoring patients treated with statins were identified. Nevertheless, the beneficial actions of statins on atrial fibrillation persisted after pooled analysis of risk-adjusted treatment effects from randomized controlled trials and observational trials (any atrial fibrillation—odds ratio, 0.64; 95% confidence interval, 0.48–0.87; new-onset atrial fibrillation—odds ratio, 0.66; 95% confidence intervals, 0.48–0.89; $P < .01$).

Conclusion: Our meta-analysis provides evidence that preoperative statin therapy is associated with a reduction in the incidence of atrial fibrillation after cardiac surgery.

En el estudio ALFA, más del 70% de los pacientes con FA tenían factores de riesgo CV o una cardiopatía subyacente

Development of a risk score for atrial fibrillation (Framingham Heart Study): a community-based cohort study

Renate B Schnabel, Lisa M Sullivan, Daniel Levy, Michael J Pencina, Joseph M Massaro, Ralph B D'Agostino Sr, Christopher Newton-Cheh, Jennifer F Yamamoto, Jared W Magnani, Thomas M Tadros, William B Kannel, Thomas J Wang, Patrick T Ellinor, Philip A Wolf, Ramachandran S Vasan, Emelia J Benjamin

Background Atrial fibrillation contributes to substantial increases in morbidity and mortality. We aimed to develop a risk score to predict individuals' absolute risk of developing the condition, and to provide a framework for researchers to assess new risk markers.

Methods We assessed 4764 participants in the Framingham Heart Study from 8044 examinations (55% women, 45–95 years of age) undertaken between June, 1968, and September, 1987. Thereafter, participants were monitored for the first event of atrial fibrillation for a maximum of 10 years. Multivariable Cox regression identified clinical risk factors associated with development of atrial fibrillation in 10 years. Secondary analyses incorporated routine echocardiographic measurements (5152 participants, 7156 examinations) to reclassify the risk of atrial fibrillation and to assess whether these measurements improved risk prediction.

Findings 457 (10%) of the 4764 participants developed atrial fibrillation. Age, sex, body-mass index, systolic blood pressure, treatment for hypertension, PR interval, clinically significant cardiac murmur, and heart failure were associated with atrial fibrillation and incorporated in a risk score ($p<0\cdot05$, except body-mass index $p=0\cdot08$), clinical model C statistic 0·78 (95% CI 0·76–0·80). Risk of atrial fibrillation in 10 years varied with age: more than 15% risk was recorded in 53 (1%) participants younger than 65 years, compared with 783 (27%) older than 65 years. Additional incorporation of echocardiographic measurements to enhance the risk prediction model only slightly improved the C statistic from 0·78 (95% CI 0·75–0·80) to 0·79 (0·77–0·82), $p=0\cdot005$. Echocardiographic measurements did not improve risk reclassification ($p=0\cdot18$).

Interpretation From clinical factors readily accessible in primary care, our risk score could help to identify risk of atrial fibrillation for individuals in the community, assess technologies or markers for improvement of risk prediction, and target high-risk individuals for preventive measures.

Lancet 2009; 373: 739–45

Electrophysiology

Electrocardiographic predictors of atrial fibrillation

Marco V. Perez, MD,[a] Frederick E. Dewey, MD,[a] Rachel Marcus, MD,[a] Euan A. Ashley, MRCP, DPhil, MD,[a] Amin A. Al-Ahmad, MD,[a] Paul J. Wang, MD,[a] and Victor F. Froelicher, MD, FACC[a,b] *Stanford, CA*

Background Atrial fibrillation (AF) is the most prevalent arrhythmia in the United States and accounts for more than 750,000 strokes per year. Noninvasive predictors of AF may help identify patients at risk of developing AF. Our objective was to identify the electrocardiographic characteristics associated with onset of AF.

Methods This was a retrospective cohort analysis of 42,751 patients with electrocardiograms (ECGs) ordered by physician's discretion and analyzed using a computerized system. The population was followed for detection of AF on subsequent ECGs. Cox proportional hazard regression analysis was performed to test the association between these ECG characteristics and development of AF.

Results For a mean follow-up of 5.3 years, 1,050 (2.4%) patients were found to have AF on subsequent ECG recordings. Several ECG characteristics, such as P-wave dispersion (the difference between the widest and narrowest P waves), premature atrial contractions, and an abnormal P axis, were predictive of AF with hazard ratio of approximately 2 after correcting for age and sex. P-wave index, the SD of P-wave duration across all leads, was one of the strongest predictors of AF with a concordance index of 0.62 and a hazard ratio of 2.7 (95% CI 2.1-3.3) for a P-wave index >35. These were among the several independently predictive markers identified on multivariate analysis.

Conclusions Several ECG markers are independently predictive of future onset of AF. The P index, a measurement of disorganized atrial depolarization, is one of the strongest predictors of AF. The ECG contains valuable prognostic information that can identify patients at risk of AF. (Am Heart J 2009;158:622-8.)

N-Terminal Pro-B-Type Natriuretic Peptide Is a Major Predictor of the Development of Atrial Fibrillation

The Cardiovascular Health Study

Kristen K. Patton, MD; Patrick T. Ellinor, MD, PhD; Susan R. Heckbert, MD, PhD;
Robert H. Christenson, PhD; Christopher DeFilippi, MD;
John S. Gottdiener, MD; Richard A. Kronmal, PhD

Background—Atrial fibrillation (AF), the most common cardiac rhythm abnormality, is associated with significant morbidity, mortality, and healthcare expenditures. Elevated B-type natriuretic peptide levels have been associated with the risk of heart failure, AF, and mortality.

Methods and Results—The relation between N-terminal pro-B-type natriuretic peptide (NT-proBNP) and AF was studied in 5445 Cardiovascular Health Study participants with the use of relative risk regression for predicting prevalent AF and Cox proportional hazards for predicting incident AF. NT-proBNP levels were strongly associated with prevalent AF, with an unadjusted prevalence ratio of 128 for the highest quintile (95% confidence interval, 17.9 to 913.3; $P<0.001$) and adjusted prevalence ratio of 147 for the highest quintile (95% confidence interval, 20.4 to 1064.3; $P<0.001$) compared with the lowest. After a median follow-up of 10 years (maximum of 16 years), there were 1126 cases of incident AF (a rate of 2.2 per 100 person-years). NT-proBNP was highly predictive of incident AF, with an unadjusted hazard ratio of 5.2 (95% confidence interval, 4.3 to 6.4; $P<0.001$) for the development of AF for the highest quintile compared with the lowest; for the same contrast, NT-proBNP remained the strongest predictor of incident AF after adjustment for an extensive number of covariates, including age, sex, medication use, blood pressure, echocardiographic parameters, diabetes mellitus, and heart failure, with an adjusted hazard ratio of 4.0 (95% confidence interval, 3.2 to 5.0; $P<0.001$).

Conclusions—In a community-based population of older adults, NT-proBNP was a remarkable predictor of incident AF, independent of any other previously described risk factor. (***Circulation***. **2009;120:1768-1774.**)

Abstract

We explored the association of chronic AF with stroke, dementia and Alzheimer's disease (AD) among community-dwelling elderly people. The study population consisted of 685 individuals from Stockholm (The Kungsholmen Project) who were aged 78 years and were free of dementia and clinical stroke. During the 6-year follow-up, 170 subjects developed dementia, and 86 persons experienced first-ever stroke. The incidence rate (per 1000 person-years) of dementia, AD and first-ever stroke was 72.3, 52.2, and 52.2 in persons with AF and 63.8, 54.6 and 30.6 in those without AF, respectively. AF was associated with the hazard ratio of 1.8 (95%CI, 1.0–3.4) for first-ever stroke, but not significantly associated with dementia or AD.

Prevalence and prognostic significance of atrial fibrillation in outpatients with heart failure due to left ventricular systolic dysfunction

Pernille Corell [a,*], Finn Gustafsson [b], Morten Schou [a], John Markenvard [c], Tonny Nielsen [d], Per Hildebrandt [a]

Abstract

Introduction: Atrial fibrillation (AF) is common in patients with heart failure (HF) due to left ventricular systolic dysfunction (LVSD), with conflicting prognostic data. The aim of our study was to assess the prevalence and incidence of AF in patients with HF and to determine the prognostic impact of baseline AF and the development of new onset AF.

Methods and results: We included 1019 outpatients with HF due to LVSD; follow-up time ranged from 3 to 64 months. At baseline 26.4% of patients had AF. Of the 284 patients with a follow-up ECG and baseline SR, 18.7% developed new onset AF.

Patients with AF were older ($p<0.001$), more often male ($p=0.04$), and more likely to have a history of stroke ($p=0.03$), but were less likely to have IHD ($p<0.001$). Baseline rhythm was independent of LVEF and NYHA-class. Baseline AF was associated with increased all-cause mortality (HR 1.38; CI 1.07–1.78, $p=0.01$) and all-cause mortality/hospitalisation (HR 1.43; CI 1.22–1.68, $p<0.001$). When adjusted for baseline covariates, baseline AF was independently associated with an increased risk of experiencing the combined endpoint (HR 1.29; CI 1.05–1.58; $p=0.02$), but did not predict all-cause mortality. By multivariable analyses, new-onset AF was associated with increased risk of all-cause mortality/hospitalisation (HR 1.45; CI 1.05–2.00; $p=0.02$).

Conclusion: In outpatients with HF due to LVSD, AF is a common co-morbidity, which adversely affects morbidity and mortality outcomes.

A meta-analysis of the prognostic significance of atrial fibrillation in chronic heart failure

Mamas A. Mamas[1,2]*, Jane C. Caldwell[1,2], Sanoj Chacko[2], Clifford J. Garratt[1,2], Farzin Fath-Ordoubadi[2], and Ludwig Neyses[1,2]

[1]Department of Cardiology, Manchester University, Manchester, UK; and [2]Manchester Heart Centre, Manchester Royal Infirmary, Oxford Road, Manchester M13 9WL, UK

Received 2 December 2008; revised 15 April 2009; accepted 12 May 2009

Aims Atrial fibrillation (AF) is one of the commonest sustained arrhythmias in chronic heart failure (CHF), although the prognostic implications of the presence of AF in CHF remain controversial. We have therefore performed this meta-analysis to study the effects of the presence of AF on mortality in CHF patients.

Methods and results A systematic MEDLINE search for all randomized trials and observational studies in which the influence of AF on CHF mortality was investigated and meta-analysis of the mortality data was performed. A total of 16 studies were identified of which 7 were randomized trials and 9 were observational studies including 30 248 and 23 721 patients, respectively. An adjusted meta-analysis of the data revealed that the presence of AF is associated with an adverse effect on total mortality with an odds ratio (OR) of 1.40 [95% confidence interval (CI) 1.32–1.48, $P < 0.0001$] in randomized trials and an OR of 1.14 (95% CI 1.03–1.26, $P < 0.05$) in observational studies. This increase in mortality associated with the presence of AF was observed in subgroups of CHF patients with both preserved and impaired left ventricular (LV) systolic function.

Conclusion In conclusion, meta-analysis of 16 studies involving 53 969 patients suggests that the presence of AF is associated with an adverse prognosis in CHF irrespective of LV systolic function.

QoL in AF. **Quality of life (QoL) is of central importance in atrial fibrillation as both a treatment goal and an endpoint in the evaluation of new therapies. QoL appears to be impaired in the majority of patients with AF. A number of interventions for AF have been shown to improve QoL, including pharmacologic and nonpharmacologic rate control, antiarrhythmic drugs, and nonpharmacologic rhythm control strategies. This paper will review the rationale, design, strengths, and limitations of the questionnaires most commonly used to assess QoL in AF studies, and present QoL outcomes from major studies of AF interventions.**

Validating a new quality of life questionnaire for atrial fibrillation patients

Érika O.V. Braganca*, Bráulio Luna Filho, Veruska H. Maria, Daniela Levy, Angelo A.V. de Paola

La FA tiene un impacto significativo en la calidad de vida

- La FA paroxística tiene un impacto significativo en la calidad de vida de los pacientes, con independencia de la frecuencia o la duración de los síntomas.
  - Dos tercios de los pacientes comunicaron que sus síntomas alteraban moderadamente sus vidas.
  - No fue posible distinguir a esos pacientes de los que no informaron alteraciones en función de la incidencia o duración de los síntomas.

1. Van den Burg MP *et al. Neth J Med* 2005;63:170-4.
2. Hamer ME *et al. Am J Cardiol* 1994;74:826-9.

La FA tiene un impacto significativo en la calidad de vida

- **Un tercio de los pacientes con FA experimenta ansiedad o depresión, directamente relacionados con la calidad de vida.**

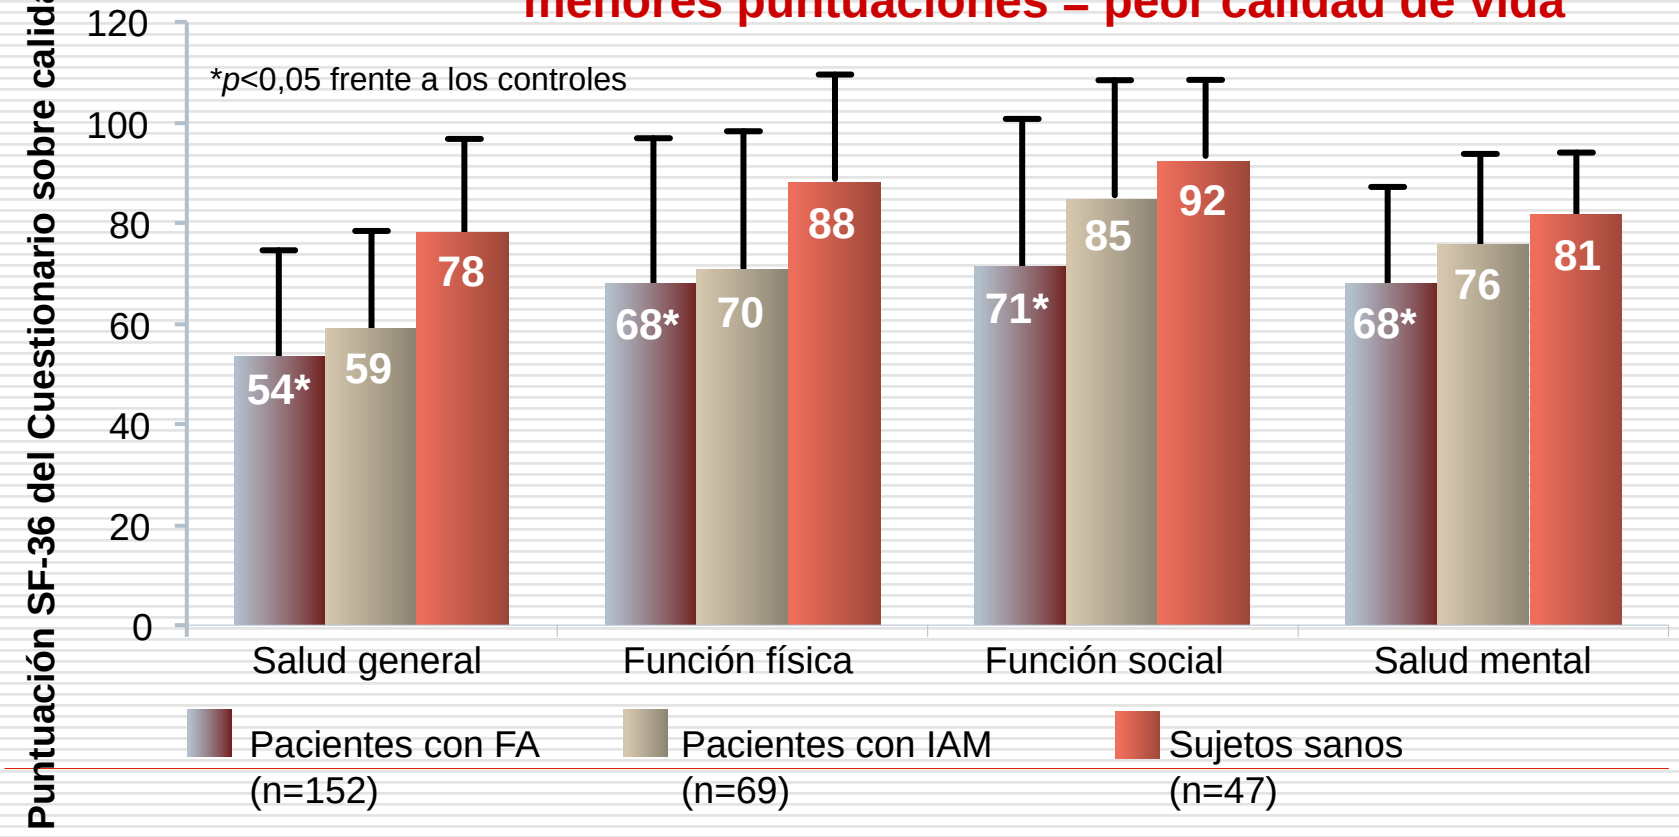
  Thrall G *et al. Chest* 2007;132:1259–64.

- **La alteración de la calidad de vida que se observa en la FA es similar a la de la ICC, el IAM y la angioplastia.**

  Dorian P *et al. J Am Coll Cardiol*. 2000;36:1303-9

La FA afecta negativamente a la calidad de vida

- La calidad de vida fue significativamente peor en los pacientes con FA



Dorian P *et al. J Am Coll Cardiol*. 2000;36:1303-9.

La FA tiene un impacto significativo en la calidad de vida

Influence of age, sex, and atrial fibrillation recurrence on quality of life outcomes in a population of patients with new-onset atrial fibrillation: The Fibrillation Registry Assessing Costs, Therapies, Adverse events and Lifestyle (FRACTAL) study

Matthew R. Reynolds, MD, MSc,[a,b] Tara Lavelle, MPH,[b] Vidal Essebag, MD, PhD,[c] David J. Cohen, MD, MSc,[a,b] and Peter Zimetbaum, MD[a,b] *Boston, MA; and Montreal, Quebec, Canada*

Background Most quality of life (QoL) data in AF have been collected from clinical trial patients. We sought to characterize symptoms and QoL in a large inception cohort of unselected patients with AF and explore the impact of age, sex, and AF clinical course on QoL measures over time.

Methods We collected symptom and QoL data on 963 patients with new onset AF enrolled in a multicenter observational registry. Patients were primarily managed with pharmacologic therapy and cardioversion. Quality of life instruments including the Medical Outcomes Study Short Form-12, University of Toronto AF Severity Scale, and the AF Symptom Checklist were completed at baseline and repeated over 2.5 years. Time-weighted QoL summary scores over the first year were calculated for each patient. Factors associated with those summary scores were explored in multivariable analyses.

Results Quality of life was moderately impaired at baseline, but quickly approached population norms and remained stable thereafter. After multivariable adjustment, female sex was strongly associated with higher symptom scores and lower QoL scores. Older (age >65 years) patients reported less prominent disease-specific impairment in QoL than younger patients. In part because 73% of patients appeared to maintain sinus rhythm for the first year, AF clinical course had a comparatively small impact on QoL during this timeframe.

Conclusions Quality of life is impaired in newly diagnosed patients with AF, but improves to normal levels with standard treatments. Within the first year after diagnosis, sex, age, and comorbid conditions are more strongly associated with QoL outcomes than the clinical course of AF itself. (Am Heart J 2006;152:1097-103.)

Peor calidad de vida: mujeres y > 65 años

La FA tiene un impacto significativo en la calidad de vida

TABLE 2
Selected Quality of Life Studies in Atrial Fibrillation

Trial Name	Population	Study Design	Measure of QoL	Results
Anti-Arrhythmic Drug Studies				
CTAF[1]	264 patients with recent paroxysmal or persistent AF without prior AAD exposure	Randomized (2:1:1) to amiodarone, sotalol, or propafenone	SF-36, Symptom Checklist, Duke Activity Status Index, University of Toronto AF Severity Scale	Modest improvements in SF-36 PCS and MCS scores and ~20% reduction in Symptom Checklist scores. No differences between groups, despite less AF in amio group
SAFE-T[34,35]	665 patients (99% men) with persistent AF	Randomized to amiodarone, sotalol, or placebo. Those in AF after 4 weeks were electrically cardioverted	SF-36, Symptom Checklist, Specific Activity Scale, University of Toronto AF Severity Scale	By intention to treat, no differences between groups at 1 year except for decreased mental health score in amio group
Rate Versus Rhythm Control Studies				
PIAF[10,16]	252 patients with AF between 7 and 360 days duration	Randomized to rhythm control (amiodarone +/− cardioversion) versus rate control. QoL data obtained at baseline and 12 months	SF-36	4/8 subscales improved in rhythm control versus 6/8 in rate control. No significant differences observed between groups
STAF[23]	AF for >4 weeks, excluding those with low and very high risk of recurrence (N = 200)	Randomized to rhythm control (cardioversion + AAD) versus rate control (drugs). QoL data obtained at baseline and 12 months	SF-36	At 12 months, 2/8 subscales improved in rhythm control group versus 5/8 in rate control group. No overall between-group differences
RACE[24]	352 patients with persistent AF included in the RACE study	Randomized to rate (drugs) or rhythm control (cardioversion, AADs). QoL data collected at baseline, 1 year, and 24–36 months	SF-36	QoL similar between groups at study end. Rate control group had improvement in 3 subscales versus 0 subscales in rhythm control group
AFFIRM[7]	25% of AFFIRM sites participated in QoL substudy (N = 716)	Patients randomly assigned to rate or rhythm control group. QoL data collected at baseline, 2 months, 12 months, and annually for 4 years	Perceived health, Ladder of life, SF-36, QoL index, Symptom Checklist	Quality of life scores improved modestly and to a similar degree in rate and rhythm control groups

AAD = antiarrhythmic drug; PCS = physical component summary score; MCS = mental component summary score.

Mejora de la calidad de vida con ambas estrategias sin diferencias entre ellas.

La FA tiene un impacto significativo en la calidad de vida

AF Catheter Ablation Studies with Quality of Life Assessment

Authors	Population	Study Design/ Ablation Approach	Measure of QoL	Results
Nonrandomized Series				
Erdogan *et al.*[38]	30 patients with paroxysmal AF refractory to multiple AADs	Linear RF ablation in the right atrium only ("catheter Maze"). QoL data obtained pre- and 3, 6, 9, 12, 24, 36 months postablation	SF-36, symptom specific checklist (locally derived)	Patients without AF recurrence (9/30) had statistically significant improvements in all eight SF-36 subscales over 2 years. Pts with AF recurrence had little change
Goldberg *et al.*[39]	33 patients with paroxysmal AF who failed multiple AADs	RF ablation of focal triggers in pulmonary veins and RA. QoL measures obtained at baseline, 1, and 3 years of follow up	SF-36	At 1 and 3 years post-ablation, significant improvements seen in all SF-36 scales except bodily pain
Pappone *et al.*[41]	589 ablation patients with drug-refractory AF (70% paroxysmal), compared with 582 patients who declined ablation	109 ablated and 102 medically treated patients did QoL surveys every 3 months for 1 year. Patients were treated with circumferential isolation of all PVs using RF	SF-36	PCS and MCS scores significantly rose from ~40 to ~50 within 6 months after ablation, but did not change in reference cohort treated with drugs
Hsu *et al.*[40]	58 pts with CHF, LVEF <45% and AF (>90% persistent or permanent)	Cohort matched (by age, sex, AF type) to additional 58 pts without CHF. RF ablation: PVI, usually with linear in ablation in LA roof and/or mitral isthmus	SF-36, Symptom Checklist	Significant improvements in Symptom Checklist and SF-36 scores reported for both groups after ablation. PCS/MCS increased 24/21 points in CHF group, 18/14 points in control group
Chen *et al.*[37]	377 consecutive patients with symptomatic AF refractory to AADs. Study focused on 94 patients with LVEF <40%	Ostial PVI performed with closed internally irrigated RF catheter; 10% also underwent cavotricuspid isthmus ablation	SF-36	Significant improvement in on all SF-36 subscales 6 months following PVI irrespective of LV function. Scores more than doubled on most scales
Weerasooriya *et al.*[43]	63 consecutive patients with symptomatic paroxysmal AF refractory to ≥2 AADs	PVI plus linear ablation in mitral isthmus and cavotricuspid isthmus using externally irrigated RF catheter. QoL data collected at baseline, 3 and 12 months	SF-36, Symptom Checklist	Significant improvement in 8/8 SF-36 subscales and Symptom Checklist scores at 3 and 12 months postablation. Largest changes in role physical (36 points) and bodily pain (31 points) scales
Tondo *et al.*[42]	105 patients with paroxysmal and persistent (75%) AF refractory to AADs. 40 patients with LVEF <40% compared to 65 without	PV "vestibule" ablation plus linear ablation in mitral isthmus and cavotricuspid isthmus using externally irrigated RF. QoL collected at baseline and 6 months	SF-36	Improvement in at least 6 SF-36 measures 6 months after ablation. Improvements similar whether or not LV dysfunction present
Randomized Studies				
Wazni *et al.*[44]	70 patients with at least monthly symptomatic PAF for at least 3 months and no prior treatment with AADs	Patients randomized to antral PVI using RF (8 mm tipped catheter) or AAD (flecainide or sotalol). QoL data obtained at enrollment and 6 months	SF-36	Improvement in QoL significantly greater (by 6–20 points) in PVI group than AAD group in 5/8 subscales of the SF-36
Oral *et al.*[15]	146 patients with "chronic" AF	Randomly assigned to 1–2 cardioversions over 3 months or ablation (circumferential PVI + linear ablation in LA roof and mitral isthmus with 8 mm RF catheter). Both groups received amiodarone for 3 months	Symptom Severity Questionnaire (locally derived, 5 symptoms)	12 months after ablation, symptom scores fell from 17±4 to 6±2 in patients without AF recurrence and from 17±4 to 12±4 in patients with AF recurrence. Recurrence less common with ablation. High rate of crossover to ablation

Mejora de la calidad de vida después ablación.

Internista

El médico especialista en la persona enferma

La medicina interna es una especialidad de larga tradición que se dedica a la atención integral del enfermo adulto. La amplia formación del internista y su conocimiento científico le permiten atender los problemas clínicos de la mayoría de los pacientes que se encuentran ingresados en un hospital.

Impacto en el día a día del internista

SEMI Sociedad Española de Medicina Interna

Impacto en el día a día del internista

La FA es una situación comórbida que requiere una valoración integral del paciente, en todas sus dimensiones, papel en que el internista se mueve con facilidad.

La insuficiencia cardíaca en los servicios de medicina interna (estudio SEMI-IC)

Grupo de Trabajo de Insuficiencia Cardíaca de la Sociedad Española de Medicina Interna (SEMI)

Impacto en el día a día del internista

FUNDAMENTO: El perfil de los pacientes con insuficiencia cardíaca (IC) varía ampliamente en sus características según el ámbito de atención de esta enfermedad. Desde el Grupo de Trabajo de Insuficiencia Cardíaca de la Sociedad Española de Medicina Interna (SEMI) se planteó un estudio multicéntrico para definir las características de los pacientes ingresados por esta enfermedad en los servicios de medicina interna españoles.

PACIENTES Y MÉTODO: Registro nacional en el que participaron voluntariamente 51 centros de toda España y que incluyó a 2.145 pacientes con esta enfermedad.

RESULTADOS: Los pacientes presentaron una media de 77,2 años de edad. El 57,3% fueron mujeres y el 42,7%, varones. Existía un elevado porcentaje de analfabetismo y nivel cultural bajo (58,9%), así como un elevado número de pacientes con cierto grado de incapacidad física y/o mental (67,4%). Existía una importante comorbilidad. La etiología más frecuente responsable de la IC fue la cardiopatía hipertensiva. Carecía de ecocardiograma una cuarta parte de los pacientes y de aquellos en los que la fracción de eyección del ventrículo izquierdo (FEVI) era conocida algo más de la mitad (53,7%) presentaba fracción de eyección normal. Los fármacos más utilizados al alta hospitalaria fueron los diuréticos (92,5%). Los inhibidores de la enzima conversiva de la angiotensina (IECA) se prescribieron en un 66,1% de los pacientes (73,4% de aquellos con disfunción sistólica conocida). Los bloqueadores beta se utilizaron en un 9,8% (12,3% de aquellos con disfunción sistólica conocida).

CONCLUSIONES: En España, los pacientes hospitalizados en servicios de medicina interna son principalmente mujeres ancianas con FEVI conservada, bajo nivel cultural y alta dependencia física. Este perfil se aleja del de los pacientes estudiados en los ensayos clínicos publicados y obliga a plantearse el abordarje más eficaz en el tratamiento, la hospitalización y el seguimiento clínico de los pacientes con IC.

Resumen

Introducción. Presentamos un resumen de los resultados de la actividad hospitalaria de los servicios de Medicina Interna (MI) del Sistema Nacional de Salud (SNS), durante el bienio 2005-2006.

Material y métodos. Se analizaron los pacientes ingresados en los servicios de MI de España en los años 2005 y 2006 según los datos obtenidos del conjunto mínimo básico de datos (CMBD), en el que se recogen datos administrativos (edad, sexo, filiación) y clínicos (un diagnóstico principal y hasta 12 diagnósticos secundarios y 19 procedimientos clínicos) de todos los pacientes ingresados en los hospitales públicos y privados de España.

Resultados. Durante este periodo se dieron en nuestro país 7.130.825 altas, ingresando a cargo de MI 1.099.652, (15,4%). Un 53,6% de los pacientes eran varones, la edad media

Impacto en el día a día del internista

Impacto en el día a día del internista

CONCLUSIONES

- La FA es la arritmia cardíaca sostenida más frecuente.
  - La FA aumenta el riesgo de ACV e insuficiencia cardíaca
  - La FA empeora el pronóstico de los pacientes con comorbilidades
  - La FA duplica el riesgo de mortalidad

CONCLUSIONES

- La FA tiene un impacto socioeconómico significativo.
- La FA afecta negativamente a la calidad de vida de los pacientes que la sufren.
- El internista es el especialista adecuado para el abordaje de la fibrilación auricular y sus comorbilidades.
